The CWHRS was supported by grant #96-IJ-CX-0020 awarded by the National Institute of Justice, Office of Justice Programs, U.S. Department of Justice. Points of view in this document do not necessarily represent the official position or policies of the U.S. Department of Justice.

Though most of the collaborators of the Chicago Women's Health Risk Study were silent partners in writing this report, they were equal partners in the project. They include Olga Becker, Nanette Benbow, Jacquelyn Campbell, Debra Clemons, James Coldren, Alicia Contreras, Eugene Craig, Roy J. Dames, Alice J. Dan, Christine Devitt, Edmund R. Donoghue, Barbara Engel, Dickelle Fonda, Charmaine Hamer, Kris Hamilton, Eva Hernandez, Tracy Irwin, Mary V. Jensen, Holly Johnson, Teresa Johnson, Candice Kane, Debra Kirby, Katherine Klimisch, Christine Kosmos, Leslie Landis, Susan Lloyd, Gloria Lewis, Christine Martin, Rosa Martinez, Judith McFarlane, Sara Naureckas, Iliana Oliveros, Angela Moore Parmley, Stephanie Riger, Kim Riordan, Roxanne Roberts, Martine Sagan, Daniel Sheridan, Wendy Taylor, Richard Tolman, Gail Walker, Carole Warshaw and Steven Whitman.

Printed by the State of Illinois.

Purpose

The Chicago Women's Health Risk Study (CWHRS) was designed to give nurses, beat officers and other primary support people information they need to know in order to help women who are experiencing violence at the hands of an intimate partner lower the risk of life-threatening injury or death. Previous research did not provide this practical information.

The purpose of the CWHRS was to identify factors indicating significant danger of life-threatening injury or death in situations in which an intimate partner is physically abusing a woman. We accomplished this by conducting a study that compared longitudinal data on abused women with similar data on women who had been killed by or who killed her intimate partner.

Who, what, where, when and how much?

Teamwork permeated all aspects of the CWHRS, from initial planning to the continued analysis and dissemination of results. The collaborative team included public and private, city, county, and state agencies, as well as talented and concerned individuals. After more than three years of collaborative planning by the Chicago Department of Public Health, Erie Family Health Center, Cook County Hospital, Chicago Mayor's Office on Domestic Violence, the Cook County Medical Examiner's Office, the Chicago Police Department, and the Illinois Criminal Justice Information Authority, the study officially began in January 1997 with funding from the National Institute of Justice (NIJ).

The CWHRS was supported by the \$312,211 NIJ grant and by substantial in-kind contributions from the Authority and the other collaborating agencies. Data gathering, documentation and initial analysis were completed in June 1999, but the collaborators continue to analyze the data and to write and disseminate reports and other products to a wide audience.

Why is the information gathered by the CWHRS important?

When nurses, beat officers, and other primary support people talk to an abused woman, they need to know the best way to respond in order to lower the risk of death or life-threatening injury. Although previous research told us who in the general population was most likely to be abused, it did not tell practitioners

about risk patterns for women who were experiencing violence. Specifically, previous research was limited in the following ways:

- it did not tell us which abused women were in a situation where the risk of serious injury or death might be especially high;
- few studies evaluated potential interventions from the woman's perspective; and
- research rarely addressed multiple barriers to safely leaving a dangerous situation.

In addition, previous research tended to measure only one or two things, and did not take into account the interaction of events and circumstances as they change over time. Practitioners need to know how changing factors, such as attempting to leave, pregnancy, children at home, or firearm availability, may affect the risk of a lethal outcome.

Field practitioners also need to know whether risk patterns differ for different racial or ethnic groups, for women in a same-sex relationship, or for pregnant women, and they need to be able to respond to women who may be in high risk situations but have not sought help from helping agencies or support networks. Prior to the CWHRS, information about the needs and best interventions for these groups was very limited.

What was the methodology of the CWHRS?

The CWHRS was designed around comparison of a "homicide sample" of all intimate partner homicides involving a woman that occurred in Chicago over a two-year period, and a "clinic/hospital sample" of detailed, longitudinal interviews with women sampled as they came into hospitals and clinics in Chicago neighborhoods where the risk for intimate partner violence was high.

Clinic/Hospital Sample

The CWHRS conducted domestic violence screening with 2,616 women as they came into a hospital or health care clinic for any kind of treatment. The screening, given as part of the clinic or hospital routine, included three short questions: current violence, current sexual abuse, and whether she was afraid to go home. Women aged 18 or older, who were in a current relationship, and who answered "yes" to at least one question screened "AW" and those who answered "no" to all questions screened "NAW." We attempted to interview all women who

screened "AW" and about 30% of the women who screened "NAW." As a result, of the 705 women we interviewed, 497 had experienced violence in the past year and 208 had not (this was the comparison group).

CWHRS study sites included the Roseland Health Center of the Chicago Department of Health, Erie Family Health Center, and Cook County Hospital. The staff of each site, and the separate clinics or practices within each site, worked hand-in-hand with the interviewers and project staff to ensure that safety and privacy standards were upheld. To ensure that high-risk but understudied groups would not be excluded from the CWHRS sample, such as women who were at high risk but who were not known to be at risk by any helping agency, we designed instruments and procedures to minimize selection bias. In addition, two-thirds of the 497 women were re-interviewed at least once over the following twelve months.

Homicide Sample

The homicide sample included all of the 87 intimate partner homicides with a woman victim or offender age 18 or older, that occurred in 1995 or 1996. There were 57 homicides with a woman victim and a man offender, 28 with a man victim and a woman offender, and two with a woman victim and offender.

There were two sources of data for the homicide sample, interviews and official or public records. We conducted detailed, face-to-face "proxy" interviews with friends, family or others who knew about the relationship, and with the woman offender herself, using questionnaires that were the same as the questionnaires used with the clinic/hospital women (to the extent possible). In addition, we gathered information from the Chicago Homicide Dataset, Medical Examiner's Office records, court records, newspapers, and other sources.

Questionnaires

Interviews covered demographics; household composition; physical health; pregnancy; substance use; mental health (depression, anxiety and post-traumatic stress disorder); firearm availability; social support network; the partner's power, control, harassment or stalking; and interventions and help-seeking.

The questionnaires and other study instruments were developed over many months of intense work by members of the collaborating team. Advocates, activists, community members, academics and researchers all took an active role in finding, evaluating and devising scales for the various dimensions we hoped to capture. The Spanish translations were done by community members (the Erie Site Advisory Board) and by two members of the collaborative team. Though the process was time-consuming, it produced translations that were correct and culturally sensitive to Latina/Hispanic women from different countries of origin.

Some of the issues covered by the CWHRS related to highly sensitive topics, and women from different cultural backgrounds might have different perceptions of these sensitive issues. Therefore, the collaborators spent a great deal of effort to word questions, and to provide a context for those questions, that would encourage women to disclose personal and sensitive experiences, to keep the questionnaire short enough so that the woman would not be fatigued, and to build in enough flexibility to encourage a natural flow of talk.

Calendar History

The 497 clinic/hospital women who had experienced violence in the past year developed a "calendar history" of every violent incident and other important events that had happened in the past year. The women told us about 4,974 incidents in the past year. The number of incidents per woman ranged from only one (29%) to 172, with 22% of the women having experienced ten or more in the past year. The most severe incident was a threat for 4% of the women, and slapping, pushing or throwing something with no injury for 23%. However, almost half (48%) suffered at least one incident we defined as "severe or life threatening" (permanent injury, being completely "beaten up," being choked or burned, internal injury, head injury, broken bones, or a threat or attack with a weapon).

In the follow-up interviews, each woman developed a calendar history for the period from the last interview to the follow-up. Of the re-interviewed women, 44% did not experience any incident in the follow-up period, 25% experienced at least one violent incident but not a severe incident, and 29% experienced at least one severe or life-threatening incident.

CWHRS key findings

The design of the CWHRS and the energy and dedication of the collaborators who made the design a reality produced a tremendously rich data set with the necessary detail and accuracy to answer the questions practitioners ask. We now know combinations of factors that indicate that a woman in an abusive situation is at high risk for serious injury or death. Some of the key findings are the following:

Leaving or trying to end the relationship

For women who left or tried to end the relationship, the potential gain was great, but there was also potential risk.

- Most clinic/hospital women (85%) who had experienced severe violence in the past year had also left or tried to end the relationship, compared to 66% of women who had experienced less severe incidents.
- Half of the women who had experienced a severe incident and who
 had left or tried to end the relationship did not experience any incident
 on follow-up. This was about the same for those who had not left or
 tried to end the relationship. Thus, overall, trying to leave did not
 increase the risk of continued violence for these women.
- Clinic/hospital women who had experienced less severe incidents in the past year and who had left or tried to end the relationship were *less* likely to experience a follow-up incident than women who had not left or tried to end the relationship.
- Clinic/hospital women who had left or tried to leave in the past year
 were less likely to experience a follow-up incident, but when they did
 experience an incident, they were more likely to experience at least
 one severe follow-up incident.
- Women homicide victims: for 40% of the incidents in which a woman was killed, an immediate precipitating factor of the fatal incident was the woman leaving or trying to end the relationship.

Risk factors for women becoming a homicide offender

Compared to women homicide victims and to clinic/hospital women, abused women homicide offenders:

- were more likely to be married, to be in a long-term relationship, and to be the mother of at least one child.
- were more likely to have experienced severe violence in the previous year, and the violence was more likely to have been increasing in frequency.
- had many fewer resources, on average (more likely to be unemployed, less likely to have a high school education, more likely to be in poorer health).

Risk factors for the fatal incident

Compared to the 4,974 non-fatal incidents, the 87 fatal incidents:

- were much more likely to involve the threat or use of a knife or gun.
- were much more likely to involve the woman being choked.
- someone was more likely to be drunk, but they were equally likely to involve drug use.

Risk factors for homicide/suicide

Ten of the 87 homicide offenders committed suicide immediately after the homicide. (Two more attempted suicide, and three committed suicide in the following year.) Compared to the 77 other fatal incidents:

- offenders who killed with a firearm were more likely to commit suicide.
- substance use was more likely to be involved in homicide/suicides.
- the offender was much more likely to be a man.
- the victim was more likely to have been trying to leave or end the relationship.
- Compared to other homicides or to the partners of clinic/hospital women, the offender was more likely to have previously tried or attempted suicide.

Severe or fatal violence did not necessarily escalate from past violence

Clinic/hospital women:

- For many women who experienced only one incident in the past year, that single incident was severe or life-threatening (27% of 143 women).
- The partner's drug use was a strong risk factor for these women.

Homicide incidents:

- In 15% of homicides where we have good information, there had been no prior violence against the woman.
- The partner's drinking or drug use was a risk factor for these homicides.

Past violence as a risk factor for homicide

In the majority of homicides (85%), the woman had experienced violence at the hands of her partner in the past year. Three specific characteristics of past violent incidents were related to future violence:

- 1. Recency (the number of days since the last incident)
 - clinic/hospital women: High probability of violence on follow-up when the last incident had happened within 30 days, regardless of that incident's severity.
 - *homicides:* For half of women victims and 75% of women offenders, the last incident had happened within 30 days of the homicide.
- 2. Frequency: incidents increasing in frequency
 - An especially important risk factor for women homicide offenders.
 - *clinic/hospital women*: High probability of violence on follow-up when there were more than ten incidents in the past year.
- 3. Type of past violence
 - Weapon threat or use (gun or knife) in the past year.
 - Choking: woman had been choked or grabbed around the neck in the past year.

Seeking Help and Interventions

Abused Women Do Seek Help

- Almost every woman had sought help after an incident in the past year, either informal (talking to someone) or formal (medical, counseling, contacting the police).
- The more serious the violence, the more likely that the woman had sought help. Women homicide victims were usually more likely than clinic/hospital women to have sought help in the past year.
- However, those few women who had not sought help were at high risk for continued violence.
- Over a third of Latina/Hispanic women did not seek help of any kind, formal or informal, even those women who had experienced severe violence.

Formal Resources (counselors or agencies, medical, criminal justice)

- Pregnant women were much less likely to seek help from any formal resource, even when they had experienced severe violence.
- Women being abused by a woman hardly ever contacted the police.
- Women homicide offenders were much more likely to have contacted the police, compared to women victims or clinic/hospital women.
- Women were much more likely to seek medical help or to contact the police than to consult an agency or counselor.

Medical Staff and the Police can be "Gate Keepers"

- Women are more likely to seek help from an agency or counselor after they seek medical help or call the police.
- By giving women support, validation, and information about counselors or agencies, medical and criminal justice staff can have a tremendous impact on a woman's life, though they may never know or get feedback about her.

Women who were actively seeking help from formal resources were also experiencing severe violence.

- Just by seeking help, a woman tells us that her situation may be highrisk.
- Seeking help in the past year was associated with severe violence on follow-up.

Implications for research

- Recognize the complexity of women's lives.
- Develop a collaborative culture.
- Measure "strangulation" as a method of violence in law enforcement and public health epidemiological data sets.

Implications for practice

Assessing risk for lethal violence:

- Ask: when did the last incident happen?
- Don't assess a woman's risk by a single incident, even the most recent.
- Be aware of abused women at risk for becoming a homicide offender.
- Pay attention to women at risk for a first, explosive incident.

Medical and law enforcement staff:

• Take advantage of opportunities to ask women if they want information about sources of help, such as an agency or counselor.

Medical staff:

• Open avenues of communication with pregnant women.

All helping professionals:

 Recognize that active help-seeking carries not only potential gain, but also potential risk.

CWHRS published reports and other products

Many of the reports listed below are available on the ICJIA web site, at http://www.icjia.state.il.us. To request any of these products, if you have a question, comment or suggestion about the project, or to ask to be put on a mailing list to receive a notice of the publication of additional products, please contact the Illinois Criminal Justice Information Authority, 120 South Riverside Plaza, Chicago, IL 60606; phone: 312-793-8550; e-mail: BBlock@icjia.state.il.us

CWHRS data sets have been archived at the National Archive of Criminal Justice Data (with all identifying information removed). They are also available on a CD, *Data on Women and Crime CD-ROM*. (CD0033, ICPSR 2972), a compilation of archived datasets published by the National Institute of Justice Data Resources Program, January, 2001. For more information, see the NACHD web site at http://www.icpsr.umich.edu/NACJD.

In addition, we are happy to provide copies of CWHRS project instruments to people who are working on similar studies. The questionnaire used in the initial interview is available on-line from the National Archive of Criminal Justice Data http://www.icpsr.umich.edu/NACJD/. The Social Support Network (SSN) Scale is cataloged in the HaPI (Health and Psychosocial Instruments) database.
